NEW QUESTION: 1

A development team has created a new flight tracker application that provides near-real-time data to users.

The application has a front end that consists of an Applicate Load Balancer (ALB) in front of two large Amazon EC2 instances in a single Availability Zone. Data is stored in a single Amazon RDS MySQL DB instance. An Amazon Route 53 DNS record points to the ALB.

Management wants the development team to improve the solution to achieve maximum reliability with the least amount of operational overhead.

Which set of actions should the team take?

- A.** Replace the DB instance with Amazon Aurora with Aurora Replicas. Deploy the application to multiple smaller EC2 instances across multiple Availability Zones in an Auto Scaling group behind an ALB
- B.** Replace the DB instance with Amazon DynamoDB global tables. Deploy the application in multiple AWS Regions. Use a Route 53 latency-based routing policy to route to the application.
- C.** Create RDS MySQL read replicas. Deploy the application to multiple AWS Regions. Use a Route 53 latency-based routing to route to the application.
- D.** Configure the DB instance as Multi-AZ. Deploy the application to two additional EC2 instances in different Availability Zones behind an ALB.

Answer: C

NEW QUESTION: 3

What are two characteristics of RIPv2? (Choose two.)

A. broadcast addressing

B. classful routing protocol

C. variable-length subnet masks

D. manual route summarization

E. uses SPF algorithm to compute path

Answer: C,D

Explanation:

RIPv2 supports VLSM networks. RIPv1 does not support VLSM.

RIPv2 supports manual route summarization

Incorrect answer:

Classful routing protocol: The original specification of RIP (RIP V1), uses classful routing.

RIPv2 included the ability to carry subnet information, thus supporting Classless Inter-Domain Routing (CIDR).

The main difference between RIPv1 and RIPv2 is classless routing. RIPv2 incorporates the addition of the network mask in the update to allow classless routing advertisements.
